Minimal Residual Disease in Melanoma: Biology, Detection and Clinical Relevance (Recent Results in Cancer Research)

Knowledge about diagnostic procedures in melanoma has increased rapidly within the past few years. Single tumor cells have been identified in normal tissue such as sentinel lymph nodes, as well as in bone marrow, peripheral blood, and other bodily fluids and cells, by molecular technologies. The introduction of polymerase chain reaction-based methods can be regarded as a prototype of this dramatic development towards molecular approaches in new diagnostic procedures. This fact opens up the possibility of clinical use in patients and of influencing treatment strategies. Considerable discrepancies have been described, however, in the success rates of these new techniques for the detection of minimal residual disease in cancer patients. Despite favorable results reported by different groups of investigators, it will take several years to define the clinical and pathophysiological relevance of new diagnostic procedures. The 1st International Symposium "Minimal Residual Disease in Melanoma: Biology, Detection and Clinical Relevance of Micrometastases", held in September 1999 in Homburg/Saar, Germany, focused on recent developments in this particular area of cancer research. The purpose of the meeting was to stimulate discussion and exchange of new data and ideas by renowned international scientists. The aim of this volume is to summarize major topics of basic research and clinical investigations presented by invited experts in this fascinating but still controversial field of melanoma research.
